BOX PATENT APPLICATION
Assistant Commissioner for Patents
Washington, D.C. 20231

Sir:

We are transmitting herewith the attached:

- Transmittal sheet, in duplicate, containing Certificate under 37 CFR 1.10.
- Utility Patent Application: Spec. 17 pgs; 20 claims; Abstract 1 pgs.
The fee has been calculated as shown below in the 'Claims as Filed' table.
- 6 sheets of informal drawings
- A signed Declaration
- A signed Power of Attorney
- Assignment of the invention to Seagate Technology, Inc., Recordation Form Cover Sheet
- A check in the amount of \$760.00 to cover the Filing Fee
- A check for \$40.00 to cover the Assignment Recording Fee.
- Return postcard

for

SLIDER SCALE PACKAGE FOR MAGNETIC RECORDING HEADS

by

David A. Sluzewski, David G. Qualey, Kevin J. Schulz, and Gordon M. Jones

Related Applications

This application claims the benefit of Provisional Application, U.S. Serial No. 60/111,307, filed on December 7, 1998, entitled to "SLIDER SCALE PACKAGE FOR MAGNETIC RECORDING HEADS", by David A. Sluzewski, David G. Qualey, Kevin J. Schulz, and Gordon M. Jones.

FIELD OF THE INVENTION

The invention relates generally to magnetic disc drives and head gimbal assemblies, more particularly, to magnetic disc drives and head gimbal assemblies having a slider scale package for magnetic recording heads.

BACKGROUND OF THE INVENTION

Modern computers require media in which digital data can be quickly stored and retrieved. Magnetizable (hard) layers on discs have proven to be a reliable media for fast and accurate data storage and retrieval. Disc drives that read data from and write data to hard discs have thus become popular components of computer systems. To access memory locations on a disc, a read/write head (also referred to as a "slider") is positioned slightly above the surface of the disc while the disc rotates beneath the read/write head at an essentially constant velocity. By moving the read/write head radially over the rotating

disc, all memory locations on the disc can be accessed. The read/write head is typically referred to as “flying” head because it includes a slider aerodynamically configured to hover above the surface on an air bearing located between the disc and the slider that is formed as the disc rotates at high speeds. The air bearing supports the read/write head

5 above the disc surface at a height referred to as the “flying height.”

In conventional disc drives, one or more hard discs are coupled to and rotate about a spindle, each disc presenting two opposite substantially flat surfaces for reading and recording. Typically, multiple rotating hard discs are stacked in a parallel relationship with minimal spacing between adjacent discs. Accordingly, the read/write heads must be

10 designed to move within the narrow space between adjacent discs and fly close to the disc surfaces. To achieve this positional capability, the read/write heads in typical disc drives are coupled to the distal end of thin, arm-like structures called head gimbal assemblies, or HGAs. The HGAs are inserted within the narrow space between adjacent discs. The HGAs are made of materials and thicknesses as to be somewhat flexible and allow a

15 measure of vertical positioning as the read/write heads hover over the surface of the rotating discs.

Each HGA is coupled at its proximal end to a rigid actuator arm. The actuator arm horizontally positions the HGA and read/write head over the disc surface. In conventional disc drives, actuator arms are stacked, forming a multi-arm head stack assembly. The head stack assembly moves as a unit under the influence of a voice coil motor to simultaneously position all head gimbal assemblies and corresponding read/write heads over the disc surfaces.

The HGA in a typical disc drive includes four components: 1) a magnetic recording (MR) head or slider, features a self-acting hydrodynamic air bearing and an

25 electromagnetic transducer for reading and writing data on a spinning magnetic disc; 2) a

gimbal, which is attached to the slider, is compliant in the slider's pitch and roll axes for the slider to follow the topography of the disc, and is rigid in yaw and in-plane axes for maintaining precise slider positioning; 3) a load beam or flexure, which is attached to the gimbal and to the actuator arm which attaches the entire HGA to the actuator. The load beam is compliant in a vertical axis to allow the slider to follow the topography of a disc, and is rigid in the in-plane axes for precise slider positioning. The load beam also supplies a downward force that counteracts the hydrodynamic lifting force developed by the slider's air bearing; and 4) a head interconnect circuit, which is disposed on the load beam and electrically coupled to the transducer of the slider. The head interconnect circuit sends the electric signals to and from the transducer of the slider/MR head. In one embodiment, the gimbal is assembled separately from the head interconnect circuit. In another embodiment, the gimbal is assembled together with the head interconnect circuit.

As the volume of HGAs in a disc drive increases from year to year, and the size of the components of the HGAs continue to shrink, the amount of labor and cost in manufacturing the HGAs becomes a large percentage of the total manufacturing cost. To decrease labor and cost, many disc drive manufacturers have implemented automation in an HGA assembling process. Circuitized or "wireless" designs for a head interconnect circuit of an HGA have been used to replace an individual or twisted pair wire designs for a head interconnect circuit. Further, to connect electrical bond pads of a slider/MR head to electrical bond pads of a head interconnect circuit in an automatic HGA line, several manufacturers have used a corner ball bonding technique between the bond pads of the slider/MR head and the bond pads of the head interconnect circuit. FIG. 2 illustrates a typical corner ball bonding assembly for electrically connecting a slider/MR head to a head interconnect circuit. Such bonding process often uses an ultrasonic bonding.

The problem associated with a corner ball bonding assembly is that it requires a three-dimensional interconnection between the bond pads of a slider/MR head and the bond pads of a head interconnect circuit. The three-dimensional interconnection requires that the slider/MR head, a conductive ball, and the head interconnect circuit be available
5 at the same time in such a small three-dimension while the slider/MR head is being bonded to the head interconnect circuit. The three-dimensional interconnection corner ball bonding technique drives expensive tooling and rigid fixturing of the slider/MR head. Accordingly, the cost of manufacturing an HGA is still very high.

It is with respect to these and other considerations that the present invention has
10 been made.

SUMMARY OF THE INVENTION

In accordance with this invention, the above and other problems were solved by providing a flex circuit attached to the back of a slider/MR head which turns the
15 slider/MR head into a slider scale package with repositioned interconnect pads.

In one embodiment of the present invention, the flex circuit includes a conductive material, and at least one interconnect pad being electrically connected to the conductive material of the flex circuit. The interconnect pad is disposed at the back of a slider/MR head. The conductive material of the flex circuit is electrically bonded to at least one
20 bond pad of the slider/MR head.

Still in one embodiment of the present invention, the electrical bonding between the conductive material of the flex circuit and the bond pad of the slider/MR head is disposed at a front end of the slider/MR head. Alternatively, the electrical bonding between the conductive material of the flex circuit and the at least one bond pad of the
25 slider/MR head is disposed at the back of the slider/MR head. The electrical bonding

between the conductive material of the flex circuit and the at least one bond pad of the slider/MR head is disposed at the back of the slider/MR head via a bonding ball.

Alternatively, the electrical bonding between the conductive material of the flex circuit and the at least one bond pad of the slider/MR head is disposed at a front end of the

5 slider/MR head via a bonding ball.

Further in one embodiment of the present invention, the slider scale package includes a head interconnect circuit which includes a conductive material. The conductive material of the head interconnect circuit is electrically bonded to the interconnect pad of the flex circuit.

10 Additionally in one embodiment of the present invention, the flex circuit includes first, second, third, and fourth interconnect pads, and the slider/MR head includes first, second, third, and fourth bond pads.

Yet in one embodiment of the present invention, the first and second bond pads are electrically coupled to a first pair of positive and negative polarities of the slider/MR head for reading data, respectively. The third and fourth bond pads are electrically coupled to a second pair of positive and negative polarities of the slider/MR head for writing data, respectively.

Still in one embodiment of the present invention, the first, second, third, and fourth interconnect pads are arranged such that the polarities of the bond pads of the slider/MR head match with polarities from the head interconnect circuit. In one embodiment, the first and second interconnect pads are electrically connected to the first and second bond pads of the slider/MR head, respectively, and the third and fourth interconnect pads are electrically connected to the third and fourth bond pads of the slider/MR head, respectively. Alternatively, the first and second interconnect pads are electrically connected to the second and first bond pads of the slider/MR head,

respectively, and the third and fourth interconnect pads are electrically connected to the fourth and third bond pads of the slider/MR head, respectively.

Further in one embodiment of the present invention, a plurality of flex circuits are made in a sheet format and are dividable into a plurality of individual flex circuits.

5 Yet in one embodiment of the present invention, the bonding of the conductive material of the flex circuit to the slider/MR head and the bonding of the interconnect pad of the flex circuit to the conductive material of the head interconnect circuit can be done in a separate automated process.

In one embodiment of the present invention, a head gimbal assembly (HGA) for 10 supporting a slider/MR head in a disc drive includes a suspension supporting the slider/MR head; a head interconnect circuit being attached to and disposed along the suspension, the head interconnect circuit including a conductive material; and a slider scale package for electrically coupling the slider/MR head to the head interconnect circuit, wherein the slider scale package comprises a flex circuit attached to the back of 15 the slider/MR head which turns the slider/MR head into the slider scale package with at least one interconnect pad disposed at the back of the slider/MR head. The interconnect pad of the flex circuit is electrically bonded to the conductive material of the head interconnect circuit.

Still in one embodiment of the present invention, the flex circuit further includes a 20 conductive material, and the slider/MR head includes at least one bond pad. The conductive material of the flex circuit is electrically connected to the at least one interconnect pad at a first end and to the bond pad of the slider/MR head at a second end.

Further in one embodiment of the present invention, the flex circuit includes first, 25 second, third, and fourth interconnect pads, and the slider/MR head includes first, second, third, and fourth interconnect pads. The interconnect pads are arranged such that

polarities of the bond pads of the head interconnect circuit match with polarities from the head interconnect circuit.

Additionally in one embodiment of the present invention, a plurality of flex circuits are made in a sheet format and are dividable into a plurality of individual flex

5 circuits.

Yet in one embodiment of the present invention, the bonding of the conductive material of the flex circuit to the slider/MR head and the bonding of the interconnect pad of the flex circuit to the conductive material of the head interconnect circuit can be done in a separate automated process.

10 One of the advantages of the present invention is that a slider scale package of a slider/MR head and a flex circuit can be placed onto a head interconnect circuit by a simple pick and place automated process. The interconnect pads of the slider scale package can be readily bonded to the head interconnect circuit in an automated process.

In one embodiment, the bonding between the interconnect pads and the conductive material of the head interconnect circuit can be done by a variety of methods, such as 15 solder, conductive adhesive, thermo-compression, etc.

One of the other advantages of the present invention is that a slider scale package can be readily attached/detached/reattached to a head interconnect circuit by soldering, thermo-compressing, or any other suitable bonding methods.

20 These and various other features as well as advantages which characterize the present invention will be apparent from a reading of the following detailed description and a review of the associated drawings.

BRIEF DESCRIPTION OF THE DRAWINGS

FIGURE 1 illustrates a top view of one embodiment of a disc drive having a circuitized head gimbal assembly (HGA) in accordance with the principles of the present invention.

5 FIGURE 2 illustrates a cross-sectional view of a typical corner ball bonding assembly for electrically connecting a slider/MR head to a head interconnect circuit in an HGA.

10 FIGURE 3 illustrates a cross-sectional view of a first embodiment of a bonding assembly having a slider scale package of a slider/MR head and a flex circuit for electrically connecting the slider/MR head to a head interconnect circuit in an HGA in accordance with the principles of the present invention.

15 FIGURE 4 illustrates one embodiment of interconnect pads disposed at the back of the slider scale package of the slider/MR head and the flex circuit of the first embodiment of the bonding assembly in accordance with the principles of the present invention.

FIGURE 5 illustrates an alternative embodiment of interconnect pads disposed at the back of the slider scale package of the slider/MR head and the flex circuit of the first embodiment of the bonding assembly in accordance with the principles of the present invention.

20 FIGURE 6 illustrates one embodiment of a plurality of flex circuits in a bar or sheet format disposed at the back of a plurality of slider/MR heads in accordance with the principles of the present invention.

25 FIGURE 7 illustrates a cross-sectional view of a second embodiment of a bonding assembly having a slider scale package of a slider/MR head and a flex circuit for electrically connecting the slider/MR head to a head interconnect circuit in an HGA in

accordance with the principles of the present invention.

FIGURE 8 illustrates one embodiment of interconnect pads disposed at the back of the slider scale package of the slider/MR head and the flex circuit of the second embodiment of the bonding assembly in accordance with the principles of the present invention.

FIGURE 9 illustrates an alternative embodiment of interconnect pads disposed at the back of the slider scale package of the slider/MR head and the flex circuit of the second embodiment of the bonding assembly in accordance with the principles of the present invention.

FIGURE 10 illustrates a cross-sectional view of a third embodiment of a bonding assembly having a slider scale package of a slider/MR head and a flex circuit for electrically connecting the slider/MR head to a head interconnect circuit in an HGA in accordance with the principles of the present invention.

FIGURE 11 illustrates a cross-sectional view of a fourth embodiment of a bonding assembly having a slider scale package of a slider/MR head and a flex circuit for electrically connecting the slider/MR head to a head interconnect circuit in an HGA in accordance with the principles of the present invention.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENT

In the following description of the present invention, reference is made to the accompanying drawings which form a part hereof, and in which is shown by way of illustration specific embodiments in which the invention may be practiced. It is understood that other embodiments may be utilized and structural changes may be made without departing from the scope of the present invention.

FIG. 1 illustrates a top view of one embodiment of a disc drive 100. The disc drive 100 includes a magnetic disc 102 mounted for rotational movement about an axis defined by a spindle 104 within a housing 106. The disc drive 100 also includes a stacked actuator system alternatively referred to as a head stack assembly 108 mounted to 5 a base plate 110 of the housing 106 and pivotally movable relative to the disc 102 about an axis 112. A cover 114 covers a portion of the head stack assembly 108. A drive controller 116 is coupled to the head stack assembly 108. As shown, the drive controller 116 is disposed outside the disc drive 100. It is appreciated that the drive controller 116 can be mounted within the disc drive 100 with a suitable connection to the head stack 10 assembly 108. It is noted that one disc 102 is illustrated in FIG. 1. It is appreciated that a stack of discs are disposed underneath the one disc 102 and mounted for rotational movement about the axis defined by the spindle 104.

The head stack assembly 108 includes an actuator arm assembly 118, an actuator arm 120, and a head gimbal assembly (HGA) 122. The HGA 122 includes a load beam 15 or flexure 124 mounted on the actuator arm 120, and a slider/MR head 126 mounted on the load beam 124. The slider/MR head 126 can be mounted on the load beam via a gimbal (not shown). The gimbal and the load beam are often referred to as a suspension of the slider/MR head (hereinafter referred to suspension 124). A transducer (not shown) is generally disposed at the front end of the slider/MR head 126 for reading data from the 20 disc 102 and writing data onto the disc 102.

A head interconnect circuit 130 (FIGs. 2, 3, 7, 10, 11) is electrically connected to the drive controller 116 at one end and electrically connected to the transducer of the slider/MR head 126 at the other end. Read/write data are thus transferred between the transducer and the drive controller 116 via the head interconnect circuit 130. Also, as 25 shown, the head interconnect circuit 130 is disposed along and mounted on the

suspension 124, preferably by an adhesive material, such as glue.

During operation, the drive controller 116 receives position information indicating a portion of the disc 102 to be accessed. The drive controller 116 may receive the position information from the operator, from a host computer, or from another suitable controller. Based on the position information, the drive controller 116 provides a position signal to the head stack assembly 108. The position signal causes the head stack assembly 108 to pivot or rotate about the axis 112. This, in turn, causes the slider/MR head 126 to move radially over the surface of the disc 102 in a generally arcuate path as indicated by arrow 132 shown in FIG. 1. Once the slider/MR head 126 is properly positioned, the drive controller 116 then executes a desired read or write operation. After the operation, the drive controller 116 then moves the head stack assembly 108 to an area, e.g. a parking area, etc. It is appreciated that different implementations can be used for the head stack assembly 108 during its non-use period. For example, the head stack assembly 108 can be moved to its original position prior to its movement to the operational position, or can be placed at the same position as the operational position.

FIG. 2 illustrates a cross-sectional view of a typical corner ball bonding assembly 125 for electrically connecting the slider/MR head 126 to the head interconnect circuit 130. The slider/MR head 126 includes one or more bond pad 133, typically four bond pads, one pair being for reading, and the other pair being for writing. One bond pad in each pair is electrically coupled to a positive polarity of the transducer, and the other bond pad in each pair is electrically coupled to a negative polarity of the transducer.

Also in FIG. 2, the head interconnect circuit 130 includes a conductive material 134, preferably copper, which is electrically connected to the drive controller 116. A corner bonding ball 136 is electrically bonded between the bond pad 133 of the slider/MR head 126 and the conductive material 134. As mentioned above, the problem with a

typical corner ball bonding is that it requires a three-dimensional interconnection between the bond pad 133 and the conductive material 134 of the head interconnect circuit 130 on the suspension 124. The three-dimensional interconnection requires that the slider/MR head 126, the corner bonding ball 136, and the circuit 130/suspension 124 be available at the same time in such a small three-dimension while the slider/MR head 126 is being bonded to the circuit 130/suspension 124. The three-dimensional interconnection corner ball bonding assembly as shown in FIG. 2 drives expensive tooling and rigid fixturing of the slider/MR head 126, particularly in an ultrasonic bonding.

FIG. 3 illustrates a cross-sectional view of one embodiment of a bonding assembly 138 in accordance with the principles of the present invention. The bonding assembly 138 includes a slider scale package 140 of a slider/MR head 142 and a flex circuit 144, and the head interconnect circuit 130 mounted on the suspension 124. The head interconnect circuit 130 includes a conductive material 134, preferably copper, which is electrically connected to the drive controller 116.

In FIG. 3, the flex circuit 144 includes a conductive material 146, preferably copper. One end of the conductive material 146 is bent upwardly and electrically connected and bonded to a bond pad 148 of the slider/MR head 142. The bonding can be done by a variety of ways, such as solder, conductive adhesive, etc. The flex circuit 144 also includes an interconnect pad 150 disposed at the other end of the conductive material 146. As shown, the interconnect pad 150 is positioned at the back of the slider/MR head 142 and is electrically bonded to the conductive material 134 of the head interconnect circuit 130. The bonding of the interconnect pad 150 to the conductive material 134 of the circuit 130 can be done by a variety of ways, such as solder, conductive adhesive, thermo-compression gold to gold, conductive polymers, etc.

Accordingly, the bonding of the flex circuit 144 to the slider/MR head 138 can be assembled separately from the bonding of the interconnect pad 150 to the conductive material 134. Accordingly, a plurality of flex circuits 144 can be made in a bar or sheet format as shown in FIG. 6. The plurality of flex circuits 144 are electrically coupled to a plurality of slider/MR heads 142 in a plurality of slider scale packages 140. The plurality of slider scale packages 140 can be divided into individual slider scale packages. The slider scale packages are easy to implement into high volume surface mount or flip chip automated processing lines. These automated processing lines can be “off the shelf” and require little or no tooling for attaching the slider scale packages to HGAs. Thus, these automated processing lines drastically reduce labor and cost in assembling an HGA.

FIGs. 4–5 illustrate two different embodiments of interconnect pads 150 which are disposed at the back of the slider scale package 140 of the slider/MR head 142 and the flex circuit 144 in accordance with the principles of the present invention. In FIG. 4, interconnect pads 150a, 150b, 150c, 150d are connected to bond pads 148a, 148b, 148c, 148d via conductive materials 146a, 146b, 146c, 146d, respectively. In one embodiment, the bond pads 148a, 148b are coupled to a first pair of positive and negative polarities, respectively, of the slider/MR head 142 for reading data. The bond pads 148c, 148d are coupled to a second pair of positive and negative polarities, respectively, of the slider/MR head 142 for writing data. The polarities from the head interconnect circuit 130 match with the polarities of the bond pads 148a–d.

When the polarities of the head interconnect circuit 130 are reversed as shown in FIG. 5, a different embodiment of a flex circuit 144' can be used. As shown in FIG. 5, interconnect pads 150a, 150b, 150c, 150d are connected to bond pads 148b, 148a, 148d, 148c via conductive materials 146a', 146b', 146c', 146d', respectively. As shown, the polarities from the head interconnect circuit 130 still match with the polarities of the bond

pads 148a, 148b, 148c, 148d. Thus, a circuit routing of the head interconnect circuit 130 does not need to be redesigned or changed when the polarities of the head interconnect circuit are reversed. Further, the arrangement of the bond pads 148a-d does not need to be modified when the polarities of the head interconnect circuit are reversed. This allows

5 to standardize a bond pad configuration at the head level.

FIG. 6 also illustrates one embodiment of a plurality of slider scale packages having a plurality of flex circuits 144 and a plurality of alternative flex circuits 144' in a bar or sheet format. As mentioned above, the slider scale packages can be divided into individual slider scale packages to be used in a plurality of head interconnect circuits. It

10 is appreciated that different arrangements of the flex circuits 144, 144' in the bar or sheet format can be used without departing the principles of the present invention.

FIG. 7 illustrates an alternative, second embodiment of a bonding assembly 152 having a slider scale package 154 of a slider/MR head 156 and a flex circuit 158 for electrically connecting the slider/MR head 156 to the head interconnect circuit 130 on the

15 suspension 124.

In FIG. 7, the flex circuit 158 includes a conductive material 160, preferably copper. One end of the conductive material 148 is bent upwardly and electrically connected and bonded to a bond pad 162 of the slider/MR head 142. The bond pad 162 is disposed at the back of the slider/MR head 156, as opposed to at the front end of the

20 slider/MR head 142 as shown in FIG. 3. Similarly, the bonding can be done by a variety of ways, such as solder, conductive adhesive, etc. The flex circuit 158 also includes an interconnect pad 164 disposed at the other end of the conductive material 160. As shown, the interconnect pad 164 is positioned at the back of the slider/MR head 156 and is electrically bonded to the conductive material 134 of the head interconnect circuit 130.

25 Similarly, the bonding of the interconnect pad 164 to the conductive material 134 of the

circuit 130 can be done by a variety of ways, such as solder, conductive adhesive, thermo-compression gold to gold, conductive polymers, etc.

Similar to FIGs. 4-5, FIGs. 8-9 illustrate two different embodiments of interconnect pads 164 for reverse polarity of the head interconnect circuit 130. The 5 interconnect pads are disposed at the back of the package of the slider/MR head 156 and the flex circuit 158,158' in accordance with the principles of the present invention.

Except that the bond pads 162a-d are disposed at the back of the slider/MR head 156, other features in FIGs. 8-9 are generally the same as those shown in FIGs. 4-5.

It is appreciated that the above slider scale package technique in accordance with 10 the principles of the present invention may be used in conjunction with a corner ball bonding technique, as shown in FIGs. 10 and 11.

FIG. 10 illustrates an alternative, third embodiment of a bonding assembly 166 having a slider scale package 168 of a slider/MR head 170 and a flex circuit 172 for electrically connecting the slider/MR head 170 to the head interconnect circuit 130 on the 15 suspension 124.

In FIG. 10, the flex circuit 172 includes a conductive material 174, preferably copper. One end of the conductive material 174 is electrically connected and bonded to a bond pad 176 of the slider/MR head 170 via a bonding ball 178. The bond pad 176 is disposed at the back of the slider/MR head 170. Similarly, the bonding can be done by a 20 variety of ways, such as solder, conductive adhesive, etc. The flex circuit 172 also includes an interconnect pad 180 disposed at the other end of the conductive material 174. As shown, the interconnect pad 180 is positioned at the back of the slider/MR head 170 and is electrically bonded to the conductive material 134 of the head interconnect circuit 130. Similarly, the bonding of the interconnect pad 180 to the conductive material 25 134 of the circuit 130 can be done by a variety of ways, such as solder, conductive

adhesive, thermo-compression gold to gold, conductive polymers, etc.

FIG. 11 illustrates an alternative, fourth embodiment of a bonding assembly 182 having a slider scale package 184 of a slider/MR head 186 and a flex circuit 188 for electrically connecting the slider/MR head 186 to the head interconnect circuit 130 on the 5 suspension 124.

In FIG. 11, the flex circuit 188 includes a conductive material 190, preferably copper. One end of the conductive material 190 is electrically connected and bonded to a bond pad 192 of the slider/MR head 186 via a bonding ball 194. The bond pad 192 is disposed at the front end of the slider/MR head 186, as opposed to at the back end of the 10 slider/MR head 186. Similarly, the bonding can be done by a variety of ways, such as solder, conductive adhesive, etc. The flex circuit 188 also includes an interconnect pad 196 disposed at the other end of the conductive material 190. As shown, the interconnect pad 196 is positioned at the back of the slider/MR head 186 and is electrically bonded to the conductive material 134 of the head interconnect circuit 130. Similarly, the bonding 15 of the interconnect pad 196 to the conductive material 134 of the circuit 130 can be done by a variety of ways, such as solder, conductive adhesive, thermo-compression gold to gold, conductive polymers, etc.

It is appreciated that in addition to a conductive material, the flex circuit 144, 144², 158, 158², 172, and 188 also includes a dielectric material, for example, polyimide. The 20 conductive material can be patterned on the dielectric material and/or laminated into a single sheet lamination, preferably covered by an insulating cover (not shown).

It is to be understood that even though numerous characteristics and advantages of various embodiments of the present invention have been set forth in the foregoing description, together with details of the structure and function of various embodiments of 25 the invention. This disclosure is illustrative only, and changes may be made in detail

within the principles of the present invention to the full extent indicated by the broad general meaning of the terms in which the appended claims are expressed.

CLAIMS

What is claimed is:

1 1. A slider scale package assembly for electrically coupling a slider/magnetic
2 recording (MR) head to a head interconnect circuit in a disc drive, comprising:
3 the slider/MR head; and
4 means for attaching to a back of the slider/MR head which turns the slider/MR
5 head into the slider scale package with at least one interconnect pad disposed at the back
6 of the slider/MR head.

1 2. A slider scale package assembly for electrically coupling a slider/magnetic
2 recording (MR) head to a head interconnect circuit in a disc drive, comprising:
3 the slider/MR head; and
4 a flex circuit attached to a back of the slider/MR head which turns the slider/MR
5 head into the slider scale package with at least one interconnect pad disposed at the back
6 of the slider/MR head.

1 3. The slider scale package assembly of claim 2, wherein the flex circuit further
2 includes a conductive material, the at least one interconnect pad is electrically connected
3 to the conductive material of the flex circuit, the slider/MR head includes at least one
4 bond pad, the conductive material of the flex circuit is electrically bonded to the at least
5 one bond pad of the slider/MR head.

1 4. The slider scale package assembly of claim 3, wherein the electrical bonding
2 between the conductive material of the flex circuit and the at least one bond pad of the
3 slider/MR head is disposed at a front end of the slider/MR head.

1 5. The slider scale package assembly of claim 3, wherein the electrical bonding
2 between the conductive material of the flex circuit and the at least one bond pad of the
3 slider/MR head is disposed at the back of the slider/MR head.

1 6. The slider scale package assembly of claim 3, wherein the electrical bonding
2 between the conductive material of the flex circuit and the at least one bond pad of the
3 slider/MR head is disposed at the back of the slider/MR head via a bonding ball.

1 7. The slider scale package assembly of claim 3, wherein the electrical bonding
2 between the conductive material of the flex circuit and the at least one bond pad of the
3 slider/MR head is disposed at a front end of the slider/MR head via a bonding ball.

1 8. The slider scale package assembly of claim 3, wherein the flex circuit includes
2 first, second, third, and fourth interconnect pads, and the slider/MR head includes first,
3 second, third, and fourth bond pads.

1 9. The slider scale package assembly of claim 8, wherein the first and second bond
2 pads are electrically coupled to a first pair of positive and negative polarities of the
3 slider/MR head for reading data, respectively, the third and fourth bond pads are
4 electrically coupled to a second pair of positive and negative polarities of the slider/MR
5 head for writing data, respectively.

1 10. The slider scale package assembly of claim 9, wherein the first, second, third, and
2 fourth interconnect pads are arranged such that the polarities of the bond pads of the head

3 interconnect circuit match with polarities from the head interconnect circuit.

1 11. The slider scale package assembly of claim 10, wherein the first and second
2 interconnect pads are electrically connected to the first and second bond pads of the
3 slider/MR head, respectively, and the third and fourth interconnect pads are electrically
4 connected to the third and fourth bond pads of the slider/MR head, respectively.

1 12. The slider scale package assembly of claim 10, wherein the first and second
2 interconnect pads are electrically connected to the second and first bond pads of the
3 slider/MR head, respectively, and the third and fourth interconnect pads are electrically
4 connected to the fourth and third bond pads of the slider/MR head, respectively.

1 13. The slider scale package assembly of claim 3, further comprising a plurality of
2 flex circuits being disposed in a sheet format.

1 14. The slider scale package assembly of claim 13, wherein the plurality of flex
2 circuits in the sheet format are dividable into a plurality of individual flex circuits.

1 15. A head gimbal assembly (HGA) for supporting a slider/magnetic recording (MR)
2 head in a disc drive, comprising:
3 a suspension supporting the slider/MR head;
4 a head interconnect circuit being attached to and disposed along the suspension,
5 the head interconnect circuit including a conductive material; and
6 a slider scale package for electrically coupling the slider/MR head to the head
7 interconnect circuit, wherein the slider scale package comprises a flex circuit attached to

8 a back of the slider/MR head which turns the slider/MR head into the slider scale package
9 with at least one interconnect pad disposed at the back of the slider/MR head, the at least
10 one interconnect pad being electrically bonded to the conductive material of the head
11 interconnect circuit.

1 16. The HGA of claim 15, wherein the flex circuit further includes a conductive
2 material, and the slider/MR head includes at least one bond pad, the conductive material
3 of the flex circuit is electrically connected to the at least one interconnect pad at a first
4 end and to the at least one bond pad of the slider/MR head at a second end.

1 17. The HGA of claim 16, wherein the flex circuit includes first, second, third, and
2 fourth interconnect pads, and the slider/MR head includes first, second, third, and fourth
3 interconnect pads.

1 18. The HGA of claim 17, wherein the first, second, third, and fourth interconnect
2 pads are arranged such that the polarities of the bond pads of the head interconnect circuit
3 match with polarities from the head interconnect circuit.

1 19. The HGA of claim 15, further comprising a plurality of flex circuits being
2 disposed in a sheet format, the plurality of flex circuits in the sheet format being dividable
3 into a plurality of individual flex circuits

1 20. The HGA of claim 16, wherein bonding of the conductive material of the flex
2 circuit to the slider/MR head and bonding of the at least one interconnect pad of the flex
3 circuit to the conductive material of the head interconnect circuit are done in a separate

4 automated process.

ABSTRACT

A slider scale package assembly in a head gimbal assembly (HGA) for electrically coupling a slider/magnetic recording (MR) head to a head interconnect circuit in a disc drive includes a flex circuit attached to the back of the slider/MR head which turns the slider/MR head into the slider scale package with at least one repositioned interconnect pad disposed at the back of the slider/MR head. The flex circuit further includes a conductive material, one end of which is electrically bonded to a bond pad of the slider/MR head, and the other end is electrically bonded to a conductive material of the head interconnect circuit via the interconnect pad. A plurality of flex circuits can be made in a sheet format and dividable into a plurality of individual flex circuits to be attached to a plurality of slider/MR heads. The bonding of the conductive material of the flex circuit to the slider/MR head and the bonding of the interconnect pad of the flex circuit to the conductive material of the head interconnect circuit can be done in a separate automated process.

MERCHANT & GOULD P.C.

United States Patent Application
DECLARATION

As a below named inventor I hereby declare that: my residence, post office address and citizenship are as stated below next to my name; that

I verily believe I am the original, first and a joint inventor of the subject matter which is claimed and for which a patent is sought on the invention entitled SLIDER SCALE PACKAGE FOR MAGNETIC RECORDING HEADS, the specification of which is attached hereto.

I hereby state that I have reviewed and understand the contents of the above-identified specification, including the claims, as amended by any amendment referred to above.

I acknowledge the duty to disclose information which is material to the patentability of this application in accordance with Title 37, Code of Federal Regulations, § 1.56 (attached hereto).

I hereby claim foreign priority benefits under Title 35, United States Code, § 119/365 of any foreign application(s) for patent or inventor's certificate listed below and have also identified below any foreign application for patent or inventor's certificate having a filing date before that of the application on the basis of which priority is claimed:

a. no such applications have been filed.
 b. such applications have been filed as follows:

FOREIGN APPLICATION(S), IF ANY, CLAIMING PRIORITY UNDER 35 USC § 119			
COUNTRY	APPLICATION NUMBER	DATE OF FILING (day, month, year)	DATE OF ISSUE (day, month, year)
ALL FOREIGN APPLICATION(S), IF ANY, FILED BEFORE THE PRIORITY APPLICATION(S)			
COUNTRY	APPLICATION NUMBER	DATE OF FILING (day, month, year)	DATE OF ISSUE (day, month, year)

I hereby claim the benefit under Title 35, United States Code, § 120/365 of any United States and PCT international application(s) listed below and, insofar as the subject matter of each of the claims of this application is not disclosed in the prior United States application in the manner provided by the first paragraph of Title 35, United States Code, § 112, I acknowledge the duty to disclose material information as defined in Title 37, Code of Federal Regulations, § 1.56(a) which occurred between the filing date of the prior application and the national or PCT international filing date of this application.

U.S. APPLICATION NUMBER	DATE OF FILING (day, month, year)	STATUS (patented, pending, abandoned)

I hereby claim the benefit under Title 35, United States Code § 119(e) of any United States provisional application(s) listed below:

U.S. PROVISIONAL APPLICATION NUMBER	DATE OF FILING (Day, Month, Year)
60/111,307	7 December 1998

I hereby declare that all statements made herein of my own knowledge are true and that all statements made on information and belief are believed to be true; and further that these statements were made with the knowledge that willful false statements and the like so made are punishable by fine or imprisonment, or both, under Section 1001 of Title 18 of the United States Code and that such willful false statements may jeopardize the validity of the application or any patent issued thereon.

§ 1.56 Duty to disclose information material to patentability.

(a) A patent by its very nature is affected with a public interest. The public interest is best served, and the most effective patent examination occurs when, at the time an application is being examined, the Office is aware of and evaluates the teachings of all information material to patentability. Each individual associated with the filing and prosecution of a patent application has a duty of candor and good faith in dealing with the Office, which includes a duty to disclose to the Office all information known to that individual to be material to patentability as defined in this section. The duty to disclose information exists with respect to each pending claim until the claim is canceled or withdrawn from consideration, or the application becomes abandoned. Information material to the patentability of a claim that is canceled or withdrawn from consideration need not be submitted if the information is not material to the patentability of any claim remaining under consideration in the application. There is no duty to submit information which is not material to the patentability of any existing claim. The duty to disclose all information known to be material to patentability is deemed to be satisfied if all information known to be material to patentability of any claim issued in a patent was cited by the Office or submitted to the Office in the manner prescribed by §§ 1.97(b)–(d) and 1.98. However, no patent will be granted on an application in connection with which fraud on the Office was practiced or attempted or the duty of disclosure was violated through bad faith or intentional misconduct. The Office encourages applicants to carefully examine:

- (1) prior art cited in search reports of a foreign patent office in a counterpart application, and
- (2) the closest information over which individuals associated with the filing or prosecution of a patent application believe any pending claim patentably defines, to make sure that any material information contained therein is disclosed to the Office.

(b) Under this section, information is material to patentability when it is not cumulative to information already of record or being made of record in the application, and

or

- (1) It establishes, by itself or in combination with other information, a prima facie case of unpatentability of a claim;
- (2) It refutes, or is inconsistent with, a position the applicant takes in:
 - (i) Opposing an argument of unpatentability relied on by the Office, or
 - (ii) Asserting an argument of patentability.

A prima facie case of unpatentability is established when the information compels a conclusion that a claim is unpatentable under the preponderance of evidence, burden-of-proof standard, giving each term in the claim its broadest reasonable construction consistent with the specification, and before any consideration is given to evidence which may be submitted in an attempt to establish a contrary conclusion of patentability.

(c) Individuals associated with the filing or prosecution of a patent application within the meaning of this section are:

- (1) Each inventor named in the application;
- (2) Each attorney or agent who prepares or prosecutes the application; and
- (3) Every other person who is substantively involved in the preparation or prosecution of the application and who is associated with the inventor, with the assignee or with anyone to whom there is an obligation to assign the application.

(d) Individuals other than the attorney, agent or inventor may comply with this section by disclosing information to the attorney, agent, or inventor.
